A NEW SPECIES OF MALLOPHAGA FROM NEW GUINEA

K. C. EMERSON, Stillwater, Oklahoma

In a small collection of Mallophaga received for determination from the Bernice P. Bishop Museum was a series from a New Guinea Wallaby which apparently represents a new species. That form is herewith described and illustrated.

Heterodoxus maai, new species

Holotype male.—General shape and chaetotaxy as shown in figure 1. Male genitalia, minus genital sac, as shown in figure 3. The male genital sac is without heavy spines found in Heterodoxus longitarsus (Piaget, 1880) as illustrated by Werneck (1941). Thoracic sternal plates with fewer setae, and the abdominal sternites with more setae than in Heterodoxus forcipatus (Mjöberg, 1919) as illustrated by Werneck (1948). The heavy spines on the prothorax are not found on Heterodoxus spiniger (Enderlein, 1909). In addition to differences in chaetotaxy, the male genitalia are distinctive. Total length, 3.47 mm.

Allotype female:—General shape and chaetotaxy, except for terminal abdominal segments, as in the male. Terminal abdominal segments as shown in figure 2. Total length, 3.45 mm.

Type host:—Dorcopsis veterum (Lesson, 1826).

Type material:—Holotype male, allotype female and paratypes of both sexes collected by T. C. Maa at Eramboe, Netherlands New Guinea on November 2, 1960. The Bernice P. Bishop Museum number is TMP 2052. The host skin is presently in the American Museum of Natural History (AMNH 193156) and was identified by H. M. Van Deusen.

Discussion:—This species is unusual in that it is the only known species of Heterodoxus with the antennae completely concealed inside lateral indentations. The dorsal and ventral surfaces of these indentations are of equal expansion. This is the first record of Mallophaga from this genus of host.
